## Chapter 35

The Nature of Light and the Laws of Geometric Optics

# PHYS 2321 <br> Week 14: Optics 

Day 2 Outline

1) Hwk: Do take home quiz on waves for Wed.

Ch. 32, MisCQs 2-12 even

$$
\text { P. } 3-5,11-15,19,21,34,35,39,41,55,56 \text {, }
$$

Due Mon
2) Ch. 32 Light: Reflection and Refraction.

* Nature of light
* Ray model (vs wave or particle models)
* Law of reflection
* Spherical mirrors

Notes: Take Home Quiz - Due now Please do course evaluations.

## The Nature of Light

- Before the beginning of the nineteenth century, light was considered to be a stream of particles
- The particles were either emitted by the object being viewed or emanated from the eyes of the viewer
- Newton was the chief architect of the particle theory of light
- He believed the particles left the object and stimulated the sense of sight upon entering the eyes

## Nature of Light Alternative View

- Christian Huygens argued that light might be some sort of a wave motion
- Thomas Young (in 1801) provided the first clear demonstration of the wave nature of light
- He showed that light rays interfere with each other
- Such behavior could not be explained by particles

## Wave nature of light: Young's double slit experiment

Diffraction occurs at each slit. The two waves interfere.

(b)

# More Confirmation of Wave Nature 

- During the nineteenth century, other developments led to the general acceptance of the wave theory of light
- Maxwell asserted that light was a form of high-frequency electromagnetic wave
- Hertz confirmed Maxwell's predictions

## More Confirmation of Wa <br> The transmitter consists of two spherical electrodes connected to an induction coil, which provides short voltage surges to the <br> spheres, setting up oscillations in the discharge between the electrodes.

- Hertz confirmed Maxwell's predictions using radio waves.
- Maxwell showed that E-M waves moved at speed of light:

$$
c=\frac{1}{\sqrt{\epsilon_{0} \mu_{0}}}=299792458 \mathrm{~m} / \mathrm{s}
$$

The receiver is a nearby loop of wire containing a second spark gap.

# Nature of light electromagnetic wave 

## Particle Nature

- Some experiments could not be explained by the wave nature of light
- The photoelectric effect was a major phenomenon not explained by waves
- When light strikes a metal surface, electrons are sometimes ejected from the surface
- The kinetic energy of the ejected electron is independent of the frequency intensity of the light

## Particle Nature, cont.

- Einstein (in 1905) proposed an explanation of the photoelectric effect that used the idea of quantization
- The quantization model assumes that the energy of a light wave is present in particles called photons
- $\mathrm{E}=\mathrm{h} f$
- h is Planck's Constant and $=6.63 \times 10-34 \mathrm{~J} \cdot \mathrm{~s}$

## Dual Nature of Light

- In view of these developments, light must be regarded as having a dual nature
- Light exhibits the characteristics of a wave in some situations and the characteristics of a particle in other situations

Measurements of the
Speed of Light

- Since light travels at a very high speed, early attempts to measure its speed were unsuccessful
- Remember c $=3.00 \times 10^{8} \mathrm{~m} / \mathrm{s}$
- Galileo tried by using two observers separated by about 10 km
- The reaction time of the observers was more than the transit time of the light

## Measurement of the Speed of Light - Roemer's Method

- Ole Roemer (1675) used astronomical observations to estimate the speed of light
- He used the period of revolution of lo, a moon of Jupiter, as Jupiter revolved around the sun

## Roemer's Method, cont.

- The periods of revolution were longer when the Earth was receding from Jupiter
- Shorter when the Earth was approaching
- Using Roemer's data, Huygens estimated the lower limit of the speed of light to be $2.3 \times 10^{8}$ $\mathrm{m} / \mathrm{s}$
- This was important because it demonstrated that light has a finite speed as well as giving an estimate of that speed

# Measurements of the Speed of Light - Fizeau's Method 

- This was the first successful method for measuring the speed of light by means of a purely terrestrial technique
- It was developed in 1849 by Armand Fizeau
- He used a rotating toothed wheel
- The distance between the wheel (considered to be the source) and a mirror was known

## Fizeau's Method, cont.

- $d$ is the distance between the wheel and the mirror
- $\Delta t$ is the time for one round trip
- Then $c=2 d / \Delta t$
- Fizeau found a value of $c=3.1 \times 10^{8} \mathrm{~m} / \mathrm{s}$

## The Ray Approximation in Geometric Optics

- Geometric optics involves the study of the propagation of light
- It uses the assumption that light travels in a straight-line path in a uniform medium and changes its direction when it meets the surface of a different medium or if the optical properties of the medium are nonuniform
- The ray approximation is used to represent beams of light

## Ray Approximation

- The rays are straight lines perpendicular to the wave fronts
- With the ray approximation, we assume that a wave moving through a medium travels in a straight line in the direction of its rays

Wave fronts

## Ray Approximation, cont.

- If a wave meets a barrier, we will assume that $\lambda \ll d$
- $d$ is the diameter of the opening
- This approximation is good for the study of mirrors, lenses, prisms, etc.

- Other effects occur for openings of other sizes

## Active Figure 35.4

- Adjust the size of the opening
- Observe the effects on the
waves
passing through

## Reflection of Light

- A ray of light, the incident ray, travels in a medium
- When it encounters a boundary with a second medium, part of the incident ray is reflected back into the first medium

This means it is directed backward into the first medium

## Specular Reflection

- Specular reflection is reflection from a smooth surface
- The reflected rays are parallel to each other
- All reflection in this text is assumed to be specular

(a)
©2004 Thomson - Brooks/Cole

## Diffuse Reflection

- Diffuse reflection is reflection from a rough surface
- The reflected rays travel in a variety of directions
- A surface behaves as a smooth surface as long as the surface variations are much smaller than the wavelength of the light

## Law of Reflection

- The normal is a line perpendicular to the surface
- It is at the point where the incident ray strikes the surface
- The incident ray makes an angle of $\theta_{1}$ with the normal
- The reflected ray makes an angle of $\theta_{1}$ with the normal

## Law of Reflection, cont.

- The angle of reflection is equal to the angle of incidence
- $\theta_{1}{ }^{\prime}=\theta_{1}$
- This relationship is called the Law of Reflection
- The incident ray, the reflected ray and the normal are all in the same plane
- Because this situation happens often, an analysis model, wave under reflection, is identified

## Active Figure 35.6

- Use the active figure to vary the angle of incidence
- Observe the effect on the angle of reflection

Normal

PLAY
ACTIVE FIGURE

## Multiple Reflections

- The incident ray strikes the first mirror
- The reflected ray is directed toward the second mirror
- There is a second reflection from the second mirror
- Apply the Law of Reflection and some geometry to determine information about the rays

## Retroreflection

- Assume the angle between two mirrors is 90。
- The reflected beam returns to the source parallel to its original path
- This phenomenon is called retroreflection
- Applications include
- Measuring the distance to the Moon
- Automobile taillights
- Traffic signs

## Refraction of Light

- When a ray of light traveling through a transparent medium encounters a boundary leading into another transparent medium, part of the energy is reflected and part enters the second medium
- The ray that enters the second medium is bent at the boundary
- This bending of the ray is called refraction

## Refraction, 2

- The incident ray, the reflected ray, the refracted ray, and the normal all lie on the same plane
- The angle of refraction depends upon the material and the angle of incidence

$$
\frac{\sin \nabla_{2}}{\sin \nabla_{1}}=\frac{v_{2}}{v_{1}}
$$

- $v_{1}$ is the speed of the light in the first medium and $\mathrm{v}_{2}$ is its speed in the second

## Refraction of Light, 3

- The path of the light through the refracting surface is reversible
- For example, a ray that travels from A to B
- If the ray originated at $B$, it would follow the line $A B$ to reach point A

## Following the Reflected and Refracted Rays

- Ray (1) is the incident ray
- Ray (2) is the reflected ray
- Ray (3) is refracted into the lucite
- Ray (4) is internally reflected in the lucite
- Ray (5) is refracted as it

(b) enters the air from the lucite

## Active Figure 35.10

- Use the active figure to vary the incident angle
- Observe the effect on the reflected and refracted rays

## Refraction Details, 1

- Light may refract into a material where its speed is lower
- The angle of refraction is less than the angle of incidence
- The ray bends toward the normal

(a)

## Refraction Details, 2

- Light may refract into a material where its speed is higher
- The angle of refraction is greater than the angle of incidence
- The ray bends away from the normal

## Active Figure 35.11

- Use the active figure to observe the light passing through three layers of material
- Vary the incident angle and the materials
- Observe the effect on the refracted ray

PLAY
ACTIVE FIGURE

## Light in a Medium

- The light enters from the left
- The light may encounter an electron
- The electron may absorb the light, oscillate, and reradiate the light
- The absorption and radiation cause the average speed of the light moving through the material to decrease

## The Index of Refraction

- The speed of light in any material is less than its speed in vacuum
- The index of refraction, $n$, of a medium can be defined as
$\mathrm{n} \square \frac{\text { speed of light in a vacuum }}{\text { speed of light in a medium }}=\frac{\mathrm{c}}{\mathrm{v}}$

## Index of Refraction, cont.

- For a vacuum, $\mathrm{n}=1$
- We assume $\mathrm{n}=1$ for air also
- For other media, $\mathrm{n}>1$
- n is a dimensionless number greater than unity
- n is not necessarily an integer

## Some Indices of Refraction

## TABLE 35.1

## Indices of Refraction

| Substance | Index of <br> Refraction | Substance | Index of <br> Refraction |
| :--- | :--- | :--- | :--- |
| Solids at $20^{\circ} \mathrm{C}$ |  | Liquids at $20^{\circ} \mathrm{C}$ |  |
| Cubic zirconia | 2.20 | Benzene | 1.501 |
| Diamond $(\mathrm{C})$ | 2.419 | Carbon disulfide | 1.628 |
| Fluorite $\left(\mathrm{CaF}_{2}\right)$ | 1.434 | Carbon tetrachloride | 1.461 |
| Fused quartz $\left(\mathrm{SiO}_{2}\right)$ | 1.458 | Ethyl alcohol | 1.361 |
| Gallium phosphide | 3.50 | Glycerin | 1.473 |
| Glass, crown | 1.52 | Water | 1.333 |
| Glass, flint | 1.66 |  |  |
| Ice $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | 1.309 | Gases at $0^{\circ} \mathrm{C}$, 1 atm |  |
| Polystyrene | 1.49 | Air | 1.000293 |
| Sodium chloride $(\mathrm{NaCl})$ | 1.544 | Carbon dioxide | 1.00045 |

Note: All values are for light having a wavelength of 589 nm in vacuum.

## Frequency Between Media

- As light travels from one medium to another, its frequency does not change
- Both the wave speed and the wavelength do change
- The wavefronts do not pile up, nor are created or destroyed at the boundary, so $f$ must stay the same

## Index of Refraction Extended

- The frequency stays the same as the wave travels from one medium to the other
- $v=f \lambda$
- $f_{1}=f_{2}$ but $\mathrm{v}_{1} \neq \mathrm{v}_{2}$ so $\lambda_{1} \neq \lambda_{2}$
- The ratio of the indices of refraction of the two media can be expressed as various ratios

$$
\frac{L_{1}}{L_{2}}=\frac{v_{1}}{v_{2}}=\frac{c / n_{1}}{c / n_{2}}=\frac{n_{2}}{n_{1}}
$$

## More About Index of Refraction

- The previous relationship can be simplified to compare wavelengths and indices: $\lambda_{1} n_{1}=$ $\lambda_{2} n_{2}$
- In air, $\mathrm{n}_{1}=1$ and the index of refraction of the material can be defined in terms of the wavelengths

$$
n=\frac{4}{4} \quad \underset{\square}{4} \frac{4 \text { in vacuum }}{4 \text { in a medium }}
$$

## Snell's Law of Refraction

- $n_{1} \sin \theta_{1}=n_{2} \sin \theta_{2}$
- $\theta_{1}$ is the angle of incidence
- $\theta_{2}$ is the angle of refraction
- The experimental discovery of this relationship is usually credited to Willebrord Snell and is therefore known as Snell's law of refraction
- Refraction is a commonplace occurrence, so identify an analysis model as a wave under refraction

## Snell's Law - Example

- Light is refracted into a crown glass slab
- $\theta_{1}=30.00^{\circ}, \theta_{2}=$ ?
- $n_{1}=1.00$ and $n_{2}=1.52$
- From Table 35.1
- $\theta_{2}=\sin ^{-1}\left(\mathrm{n}_{1} / \mathrm{n}_{2}\right) \sin \theta_{1}=$ 19.2
- The ray bends toward the normal, as expected

## Prism

- A ray of singlewavelength light incident on the prism will emerge at angle $\delta$ from its original direction of travel
- $\delta$ is called the angle of deviation
- $\Phi$ is the apex angle

## Huygens's Principle

- Huygens assumed that light is a form of wave motion rather than a stream of particles
- Huygens's Principle is a geometric construction for determining the position of a new wave at some point based on the knowledge of the wave front that preceded it

## Huygens's Principle, cont.

- All points on a given wave front are taken as point sources for the production of spherical secondary waves, called wavelets, which propagate outward through a medium with speeds characteristic of waves in that medium
- After some time has passed, the new position of the wave front is the surface tangent to the wavelets

## Huygens's Construction for a Plane Wave

- At $t=0$, the wave front is indicated by the plane $A A^{\prime}$
- The points are representative sources for the wavelets
- After the wavelets have moved a distance $c \Delta t$, a new plane $B B^{\prime}$ can be drawn tangent to the wavefronts

# Huygens's Construction for a Spherical Wave 

- The inner arc represents part of the spherical wave
- The points are representative points where wavelets are propagated
- The new wavefront is tangent at each point to the wavelet

(b)

# Huygens's Principle and the Law of Reflection 

- The law of reflection can be derived from Huygens's principle
- $A B$ is a plane wave front of incident light
- The wave at $A$ sends out a wavelet centered on $A$ toward $D$
- The wave at $B$ sends out a wavelet centered on $B$ toward $C$
- $A D=B C=c \Delta t$

# Huygens's Principle and the Law of Reflection, cont. 

- Triangle $A B C$ is congruent to triangle $A D C$
- $\cos \gamma=B C / A C$
- $\cos \gamma \dot{\gamma}=A D / A C$
- Therefore, $\cos \gamma=\cos \gamma$ and $\gamma=\gamma^{\prime}$
- This gives $\theta_{1}=\theta_{1}{ }^{\prime}$
- This is the law of reflection

# Huygens's Principle and the Law of Refraction 

- Ray 1 strikes the surface and at a time interval $\Delta$ t later, ray 2 strikes the surface
- During this time interval, the wave at $A$ sends out a wavelet, centered at $A$, toward $D$

# Huygens's Principle and the Law of Refraction, cont. 

- The wave at $B$ sends out a wavelet, centered at $B$, toward $C$
- The two wavelets travel in different media, therefore their radii are different
- From triangles $A B C$ and ADC, we find
$\sin \nabla_{1}=\frac{B C}{A C}=\frac{v_{1} \Delta t}{A C}$ and $\sin \nabla_{2}=\frac{A D}{A C}=\frac{v_{2} \Delta t}{A C}$

## Huygens's Principle and the Law of Refraction, final

- The preceding equation can be simplified to
$\frac{\sin V_{1}}{\sin V_{2}}=\frac{V_{1}}{V_{2}}$
But $\frac{\sin \mathrm{F}_{1}}{\sin \mathrm{~F}_{2}}=\frac{c / n_{1}}{c / n_{2}}=\frac{n_{2}}{n_{1}}$
and so $n_{1} \sin \mathrm{P}_{1}=n_{2} \sin \mathrm{P}_{2}$
- This is Snell's law of refraction

## Dispersion

- For a given material, the index of refraction varies with the wavelength of the light passing through the material
- This dependence of $n$ on $\lambda$ is called dispersion
- Snell's law indicates light of different wavelengths is bent at different angles when incident on a refracting material

## Variation of Index of Refraction with Wavelength

- The index of refraction for a material generally decreases with increasing wavelength
- Violet light bends more than red light when passing into a refracting material

## Refraction in a Prism

- Since all the colors have different angles of deviation, white light will spread out into a spectrum
- Violet deviates the most
- Red deviates the least
- The remaining colors are in between

## The Rainbow

- A ray of light strikes a drop of water in the atmosphere
- It undergoes both reflection and refraction
- First refraction at the front of the drop
- Violet light will deviate the most
- Red light will deviate the least

## The Rainbow, 2

- At the back surface the light is reflected
- It is refracted again as it returns to the front surface and moves into the air
- The rays leave the drop at various angles
- The angle between the white light and the most intense violet ray is $40^{\circ}$
- The angle between the white light and the most intense red ray is $42^{\circ}$

## Active Figure 35.23

- Use the
active figure to vary the point at which the sunlight enters the raindrop
- Observe the angles and verify the maximum angles

## Observing the Rainbow

- If a raindrop high in the sky is observed, the red ray is seen
- A drop lower in the sky would direct violet light to the observer
- The other colors of the spectra lie in between the red and the violet

## Double Rainbow

- The secondary rainbow is fainter than the primary
- The colors are reversed
- The secondary rainbow arises from light that makes two reflections from the interior surface before exiting the raindrop
- Higher-order rainbows are possible, but their intensity is low

## Total Internal Reflection

- A phenomenon called total internal reflection can occur when light is directed from a medium having a given index of refraction toward one having a lower index of refraction

## Possible Beam Directions

- Possible directions of the beam are indicated by rays numbered 1 through 5
- The refracted rays are bent away from the normal since $n_{1}>n_{2}$

Normal

## Critical Angle

- There is a particular angle of incidence that will result in an angle of refraction of $90^{\circ}$
- This angle of incidence is called the critical angle, $\theta_{\mathrm{C}}$

$$
\sin \nabla_{c}=\frac{n_{2}}{n_{1}}\left(\text { for } n_{1}>n_{2}\right)
$$

$$
n_{2}<n_{1}
$$

## Active Figure 35.25

- Use the active figure to vary the incident angle
- Observe the effect on the refracted ray

PLAY
ACTIVE FIGURE

## Critical Angle, cont.

- For angles of incidence greater than the critical angle, the beam is entirely reflected at the boundary
- This ray obeys the law of reflection at the boundary
- Total internal reflection occurs only when light is directed from a medium of a given index of refraction toward a medium of lower index of refraction

## Fiber Optics

- An application of internal reflection
- Plastic or glass rods are used to "pipe" light from one place to another
- Applications include
- Medical examination of internal organs

- Telecommunications

## Fiber Optics, cont.

- A flexible light pipe is called an optical fiber
- A bundle of parallel fibers (shown) can be used to construct an optical transmission line

## Construction of an Optical Fiber

- The transparent core is surrounded by cladding
- The cladding has a lower $n$ than the core
- This allows the light in the core to experience total internal reflection
- The combination is surrounded by the jacket
