# Chapter 16

Sound Waves

PHYS 2321
Week 13: Sound

Day 3 Outline

1) Hwk: Ch. 16, P. 2,3,5,7,11,17,20,30,33,47,49 Due
                                    Mon after break

2) Ch. 16 – Sound
    * (Sound waves in terms of P, ρ, s) – skim
    * Speed of sound – temperature dependence
    * Demo: resonant tube
    * Power and intensity of sound waves

Notes: Ch. 29 hwk mean = 9.4/10

PHYS 2321
Week 14: Sound/Optics

Day 1 Outline

1) Hwk: Ch. 16, P. 2,3,5,7,11,17,20,30,33,47,49 Due <3 pm
         Do take home quiz on waves for Wed.
         Ch. 32, MiscQs ____ P. _____ Due Mon

2) Ch. 16 – Sound
   * Power and intensity of sound waves
   * Beats.   [Demo]
3) Ch. 32 Light: Reflection and Refraction.
   * Ray model (vs wave or particle models)
   * Law of reflection

Notes: Please do course evaluations.
Introduction to Sound Waves

- Sound waves are longitudinal waves
- They travel through any material medium
- The speed of the wave depends on the properties of the medium
- The mathematical description of sinusoidal sound waves is very similar to sinusoidal waves on a string

Categories of Sound Waves

- The categories cover different frequency ranges
- **Audible waves** are within the sensitivity of the human ear
  - Range is approximately 20 Hz to 20 kHz
- **Infrasonic waves** have frequencies below the audible range
- **Ultrasonic waves** have frequencies above the audible range
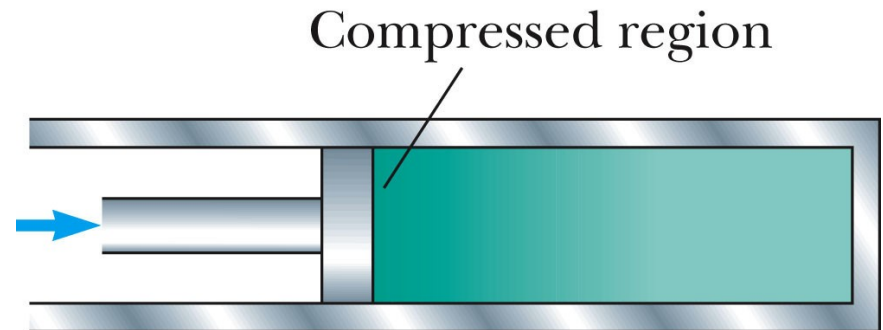

Speed of Sound Waves

- Use a compressible gas as an example with a setup as shown at right
- Before the piston is moved, the gas has uniform density
- When the piston is suddenly moved to the right, the gas just in front of it is compressed
 - Darker region in the diagram

Undisturbed gas

(a)
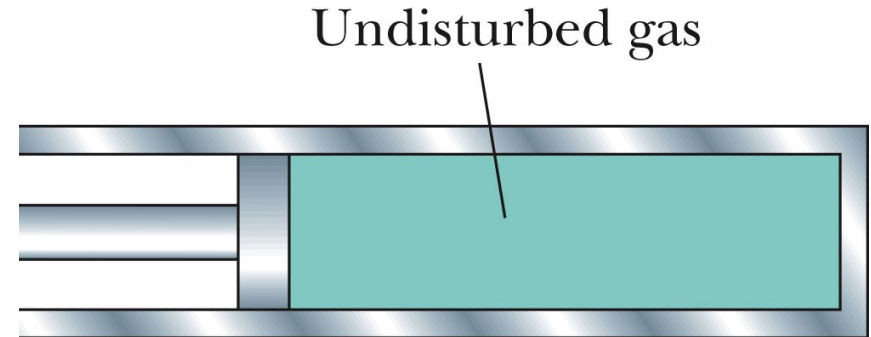

© 2007 Thomson Higher Education
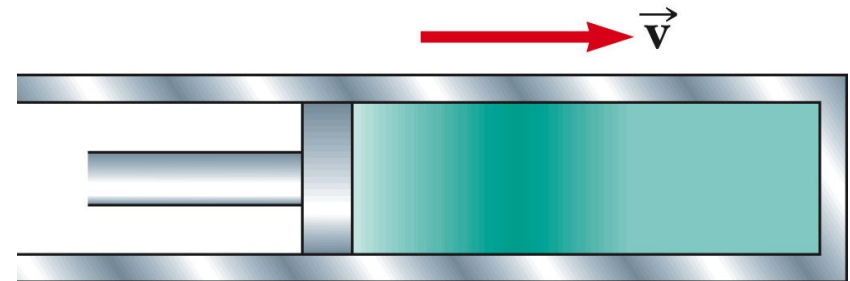

Compressed region

(b)

© 2007 Thomson Higher Education
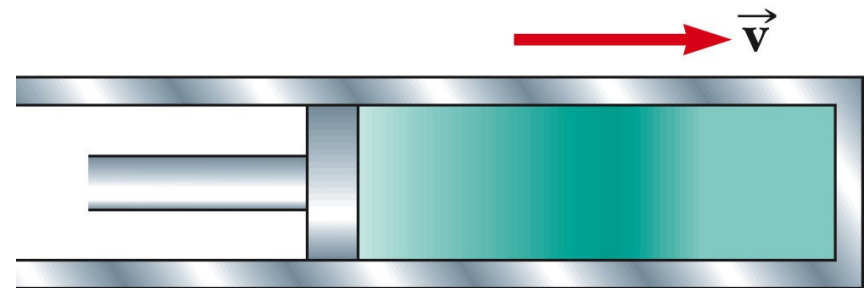

Speed of Sound Waves, cont

- When the piston comes to rest, the compression region of the gas continues to move
  - This corresponds to a longitudinal pulse traveling through the tube with speed v
  - The speed of the piston is not the same as the speed of the wave

(c)

Speed of Sound Waves, General

- The speed of sound waves in a medium depends on the compressibility and the density of the medium

- The compressibility can sometimes be expressed in terms of the elastic modulus of the material

- The speed of all mechanical waves follows a general form:

$$v = \sqrt{\frac{\text{elastic property}}{\text{inertial property}}}$$

Speed of Sound in Liquid or Gas

- The bulk modulus of the material is B
- The density of the material is ρ
- The speed of sound in that medium is
$$v = \sqrt{\frac{B}{\rho}}$$

Speed of Sound in Air

- The speed of sound also depends on the temperature of the medium

- This is particularly important with gases

- For air, the relationship between the speed and temperature is

$$v = \left(331\, m/s\right)\left(1 + \frac{Tc}{273}\right)$$

  - The 331 m/s is the speed at 0° C
  - T_C is the air temperature in Celsius

Speed of Sound in Gases, Example Values

Medium	v (m/s)
Gases	
Hydrogen (0°C)	1 286
Helium (0°C)	972
Air (20°C)	343
Air (0°C)	331
Oxygen (0°C)	317

Speed of Sound in Liquids, Example Values

Medium	v (m/s)
Liquids at 25°C	
Glycerol	1 904
Seawater	1 533
Water	1 493
Mercury	1 450
Kerosene	1 324
Methyl alcohol	1 143
Carbon tetrachloride	926

Speeds are in m/s

Speed of Sound in Solids, Example Values
Medium	v (m/s)
Solids[a]	
Pyrex glass	5 640
Iron	5 950
Aluminum	6 420
Brass	4 700
Copper	5 010
Gold	3 240
Lucite	2 680
Lead	1 960
Rubber	1 600

Speeds are in m/s; values are for bulk solids

Periodic Sound Waves, Example

- A longitudinal wave is propagating through a gas-filled tube

- The source of the wave is an oscillating piston

- The distance between two successive compressions (or rarefactions) is the wavelength

- Use the active figure to vary the frequency of the piston
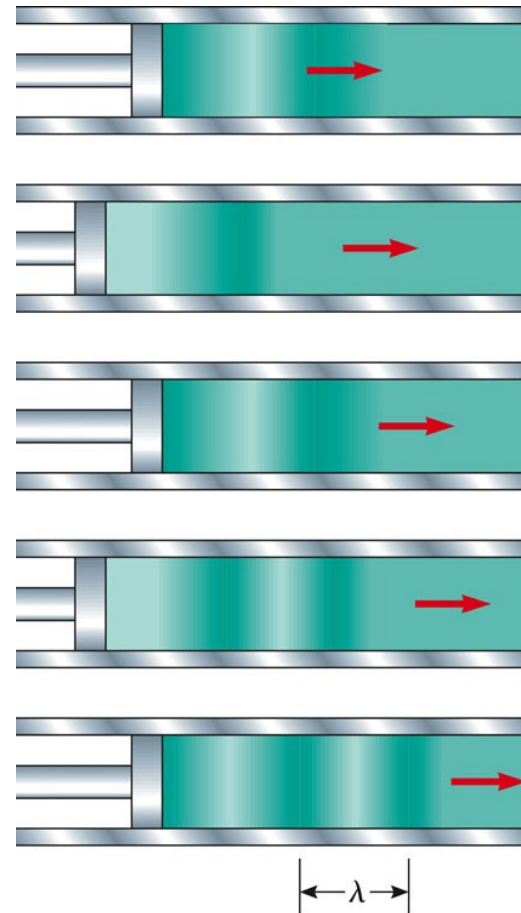

Periodic Sound Waves, cont

- As the regions travel through the tube, any small element of the medium moves with simple harmonic motion parallel to the direction of the wave

- The harmonic position function is

$$s\,(x,\,t) = s_{max}\,\cos\,(kx - \omega t)$$

  - s_{max} is the maximum position from the equilibrium position

  - This is also called the displacement amplitude of the wave
Periodic Sound Waves, Pressure

- The variation in gas pressure, ΔP, is also periodic

$$\Delta P = \Delta P_{max} \sin (kx - \omega t)$$

- ΔP_{max} is the pressure amplitude
- It is also given by $\Delta P_{max} = \rho v \omega s_{max}$
- k is the wave number (in both equations)
- ω is the angular frequency (in both equations)

# Periodic Sound Waves, final

- A sound wave may be considered either a displacement wave or a pressure wave
- The pressure wave is 90º out of phase with the displacement wave
  - The pressure is a maximum when the displacement is zero, etc.

© 2007 Thomson Higher Education
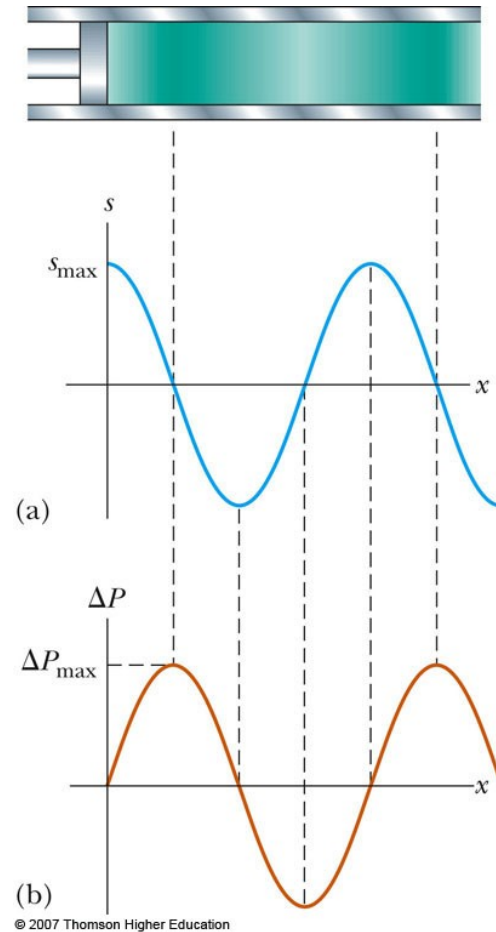

Energy of Periodic Sound Waves

- Consider an element of air with mass Δm and length Δx
- The piston transmits energy to the element of air in the tube
- This energy is propagated away from the piston by the sound wave

Area = A

Δm

$\vec{v}$

Δx

© 2007 Thomson Higher Education

Energy, cont.

- The kinetic energy in one wavelength is

  $$K_\lambda = \tfrac{1}{4}(\rho A)\omega^2\, s_{max}^2 \lambda$$

- The total potential energy for one wavelength is the same as the kinetic

- The total mechanical energy is

 $$E_\lambda = K_\lambda + U_\lambda = \tfrac{1}{2}(\rho A)\omega^2\, s_{max}^2 \lambda$$

Power of a Periodic Sound Wave

- The rate of energy transfer is the power of the wave

$$\wp = \frac{\Delta E}{\Delta t} = \frac{E_\lambda}{T} = \frac{1}{2}\rho A v \omega^2 s_{max}^2$$
- This is the energy that passes by a given point during one period of oscillation

Intensity of a Periodic Sound Wave

- The **intensity,** *I,* of a wave is defined as the power per unit area
  - This is the rate at which the energy being transported by the wave transfers through a unit area, *A*, perpendicular to the direction of the wave
$$I = \frac{\wp}{A}$$

Intensity, cont

- In the case of our example wave in air,

  $$I = \tfrac{1}{2}\, \rho v (\omega s_{max})^2$$

- Therefore, the intensity of a periodic sound wave is proportional to the

  - Square of the displacement amplitude
  - Square of the angular frequency
- In terms of the pressure amplitude,

 $$I = \frac{(\Delta P_{max})^2}{2\rho v}$$

Intensity of a Point Source

- A **point source** will emit sound waves equally in all directions
  - This results in a **spherical wave**
- Identify an imaginary sphere of radius r centered on the source
- The power will be distributed equally through the area of the sphere

Intensity of a Point Source, cont

- $I = \dfrac{P_{av}}{A} = \dfrac{P_{av}}{4\pi r^2}$

- This is an inverse-square law
  - The intensity decreases in proportion to the square of the distance from the source

Wave front→

Source

λ

Ray

Sound Level
- The range of intensities detectable by the human ear is very large

- It is convenient to use a logarithmic scale to determine the intensity level, β

$$\beta = 10 \log \left(\frac{I}{I_o} \right)$$

Sound Level, cont

- I_0 is called the **reference intensity**
    - It is taken to be the threshold of hearing
    - $I_0 = 1.00 \times 10^{-12}$ W/ m^2
    - I is the intensity of the sound whose level is to be determined
- β is in decibels (dB)
- Threshold of pain: $I = 1.00$ W/m^2; $\beta = 120$ dB
- Threshold of hearing: $I_0 = 1.00 \times 10^{-12}$ W/ m^2 corresponds to $\beta = 0$ dB

Sound Level, Example

- What is the sound level that corresponds to an intensity of 2.0×10^{-7} W/m^2 ?

$\beta = 10 \log (2.0 \times 10^{-7}$ W/m^2 / 1.0×10^{-12} W/m$^2) = 10 \log 2.0 \times 10^5 = 53$ dB

- Rule of thumb: A doubling in the intensity is approximately equivalent to an increase of 3 dB

Sound Levels

**TABLE 17.2**

Sound Levels

| Source of Sound	β (dB)
Nearby jet airplane	150
Jackhammer; machine gun	130
Siren; rock concert	120
Subway; power lawn mower	100
Busy traffic	80
Vacuum cleaner	70
Normal conversation	50
Mosquito buzzing	40
Whisper	30
Rustling leaves	10
Threshold of hearing	0

Loudness and Intensity

- Sound level in decibels relates to a *physical measurement* of the strength of a sound
- We can also describe a *psychological "measurement"* of the strength of a sound
- Our bodies "calibrate" a sound by comparing it to a reference sound
- This would be the threshold of hearing
- Actually, the threshold of hearing is this value for 1000 Hz
Loudness and Frequency, cont

- There is a complex relationship between loudness and frequency
- The white area shows average human response to sound
- The lower curve of the white area shows the threshold of hearing
- The upper curve shows the threshold of pain

Sound level β (dB)

Infrasonic frequencies | Sonic frequencies | Ultrasonic frequencies

Whispered speech

Frequency f (Hz)

© 2007 Thomson Higher Education

The Doppler Effect

- The **Doppler effect** is the apparent change in frequency (or wavelength) that occurs because of motion of the source or observer of a wave
  - When the relative speed of the source and observer is higher than the speed of the wave, the frequency appears to increase
  - When the relative speed of the source and observer is lower than the speed of the wave, the frequency appears to decrease
Doppler Effect, Observer Moving

- The observer moves with a speed of v_o

- Assume a point source that remains stationary relative to the air

- It is convenient to represent the waves with a series of circular arcs concentric to the source

  - These surfaces are called *wave fronts*
© 2007 Thomson Higher Education
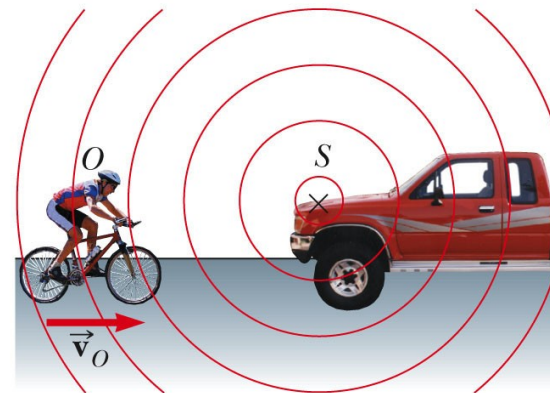

Doppler Effect, Observer Moving, cont

- The distance between adjacent wave fronts is the wavelength

- The speed of the sound is v, the frequency is f, and the wavelength is λ

- When the observer moves toward the source, the speed of the waves relative to the observer is v ' = v + v_o

  - The wavelength is unchanged
Doppler Effect, Observer Moving, final

- The frequency heard by the observer, f ', appears higher when the observer approaches the source

$$f' = \left(\frac{v + v_o}{v}\right)f$$

- The frequency heard by the observer, f ', appears lower when the observer moves away from the source

$$f' = \left(\frac{v - v_o}{v}\right)f$$

Doppler Effect, Source Moving

- Consider the source being in motion while the observer is at rest

- As the source moves toward the observer, the wavelength appears shorter

- As the source moves away, the wavelength appears longer

  - Use the active figure to adjust the speed and observe the results

Observer B

S

$\vec{\mathbf{v}}_S$

λ'

Observer A

(a)

© 2007 Thomson Higher Education
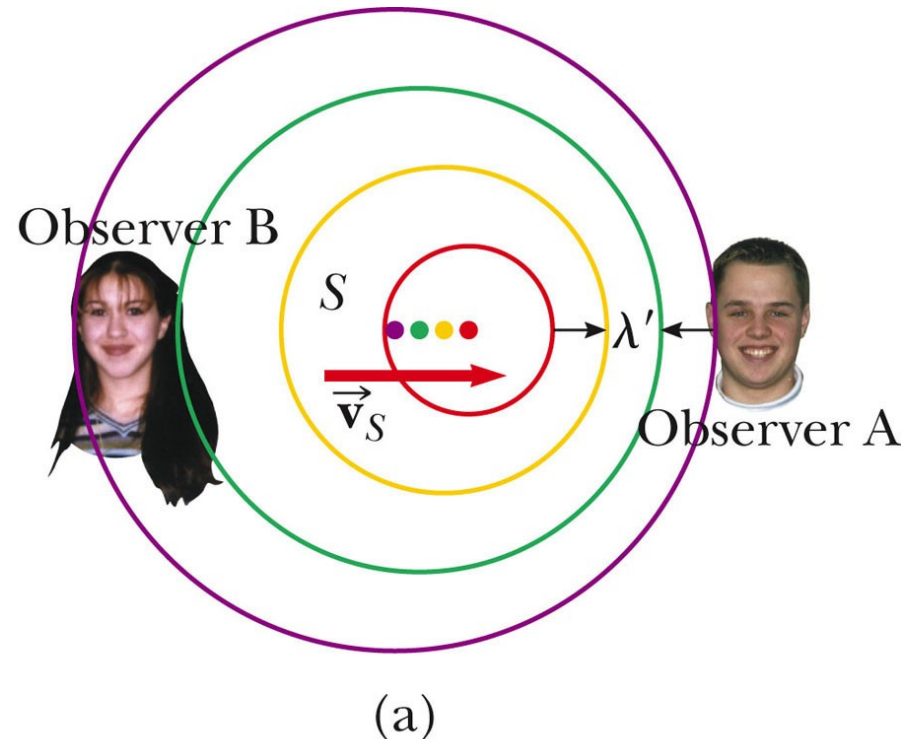

# Doppler Effect, Source Moving, cont

- When the source is moving toward the observer, the apparent frequency is higher

$$f' = \left(\frac{v}{v - v_s} \right) f$$

- When the source is moving away from the observer, the apparent frequency is lower

$$f' = \left(\frac{v}{v + v_s} \right) f$$

Doppler Effect, General

- Combining the motions of the observer and the source
$$f' = \left(\frac{v + v_o}{v - v_s} \right) f$$

- The signs depend on the direction of the velocity
  - A positive value is used for motion of the observer or the source *toward* the other
 - A negative sign is used for motion of one *away from* the other

Doppler Effect, final

- Convenient rule for signs
  - The word "toward" is associated with an increase in the observed frequency
  - The words "away from" are associated with a decrease in the observed frequency
- The Doppler effect is common to all waves
- The Doppler effect does not depend on distance
Doppler Effect, Water Example

- A point source is moving to the right
- The wave fronts are closer on the right
- The wave fronts are farther apart on the left
(b)

Doppler Effect, Submarine Example

- Sub A (source) travels at 8.00 m/s emitting at a frequency of 1400 Hz

- The speed of sound is 1533 m/s

- Sub B (observer) travels at 9.00 m/s

- What is the apparent frequency heard by the observer as the subs approach each other? Then as they recede from each other?
Doppler Effect, Submarine Example cont

- Approaching each other:

$$f' = \left(\frac{v + v_o}{v - v_s}\right) f = \left(\frac{1533 \text{ m/s} + (+9.00 \text{ m/s})}{1533 \text{ m/s} - (+8.00 \text{ m/s})}\right)(1400\, Hz)$$
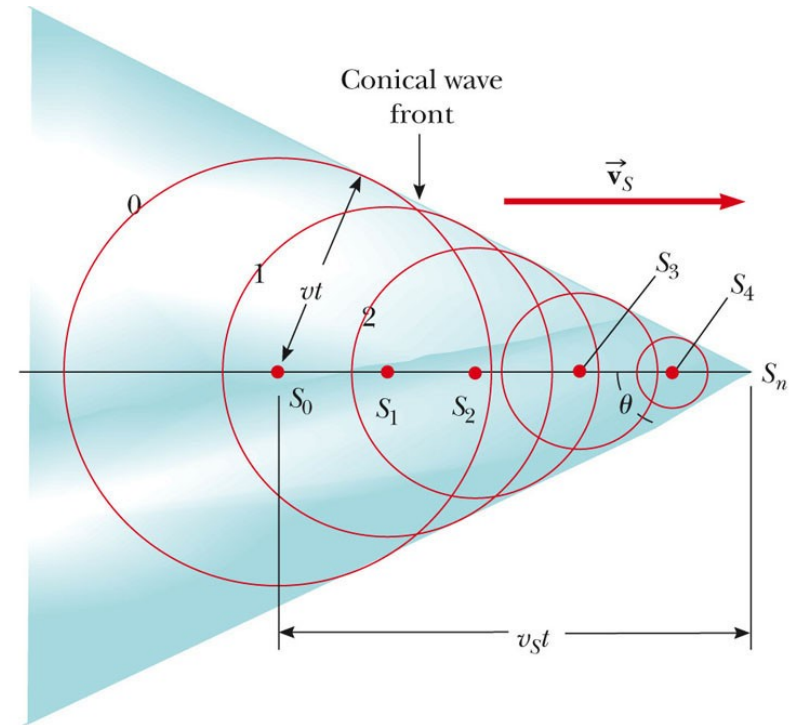

$$= 1416\, Hz$$

- Receding from each other:

$$f' = \left(\frac{v + v_o}{v - v_s}\right) f = \left(\frac{1533 \text{ m/s} + (-9.00 \text{ m/s})}{1533 \text{ m/s} - (-8.00 \text{ m/s})}\right)(1400\, Hz)$$
$$= 1385\, Hz$$

Shock Wave

- The speed of the source can *exceed* the speed of the wave
- The envelope of these wave fronts is a cone whose apex half-angle is given by sin $\theta = v/v_S$
  - This is called the *Mach angle*

Conical wave front

$\vec{v}_S$

vt

S_0 S_1 S_2 S_3 S_4 S_n

θ

$v_S t$

(a)

Mach Number

- The ratio v_s / v is referred to as the *Mach number*

- The relationship between the Mach angle and the Mach number is
$$\sin \theta = \frac{vt}{v_s t} = \frac{v}{v_s}$$

Shock Wave, final

- The conical wave front produced when $v_s > v$ is known as a shock wave

  - This is supersonic

- The shock wave carries a great deal of energy concentrated on the surface of the cone

- There are correspondingly great pressure variations
(b)

Sound Recording

- Encoding sound waveforms began as variations in depth of a continuous groove cut in tin foil wrapped around a cylinder

- Sound was then recorded on cardboard cylinders coated with wax

- Next were disks made of shellac and clay

- In 1948, plastic phonograph disks were introduced

# Digital Recording

(a)
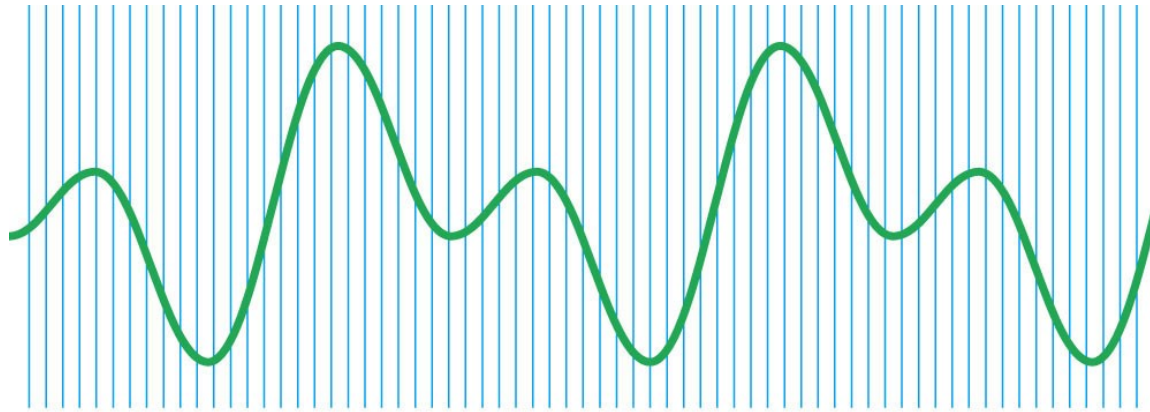

© 2007 Thomson Higher Education

- In digital recording of sound, information is converted to binary code

- The waveforms of the sound are sampled

- During the sampling, the pressure of the wave is sampled and converted into a voltage

- The graph above shows the sampling process

Digital Recording, 2

- These voltage measurements are then converted to binary numbers (1's and 0's)
  - Binary numbers are expressed in base 2
- Generally, the voltages are recorded in 16-bit "words"
  - Each bit is a 1 or a 0
- The number of voltage levels that can be assigned codes is $2^{16} = 65\ 536$

Digital Recording, 3

- The strings of ones and zeroes are recorded on the surface of the compact disc
- There is a laser playback system that detects lands and pits
  - Lands are the untouched regions
    - They are highly reflective
  - Pits are areas burned into the surface
    - They scatter light instead of reflecting it
Digital Recording, final

- The binary numbers from the CD are converted back into voltages

- The waveform is reconstructed

- Advantages

  - High fidelity of the sound

  - There is no mechanical wear on the disc

    - The information is extracted optically
Motion Picture Sound

- Early movies recorded sound on phonograph records
  - They were synchronized with the action on the screen
- Then a variable-area optical soundtrack was introduced
  - The sound was recorded on an optical track on the edge of the film
  - The width of the track varied according to the sound wave
Motion Picture Sound, cont

- A photocell detecting light passing through the track converted the varying light intensity to a sound wave

- Problems
  - Dirt or fingerprints on the track can cause fluctuations and loss of fidelity

# Systems of Motion Picture Sound – Original

- Cinema Digital Sound (CDS)
  - First used in 1990
  - No backup
  - No longer used
  - Introduced the use of 5.1 channels of sound:
    - Left, Center, Right, Right Surround, Left Surround and Low Frequency Effects (LFE)

Systems of Motion Picture Sound – Current

- Dolby Digital
  - 5.1 channels stored between sprocket holes on the film
  - Has an analog backup
  - First used in 1992
- Digital Theater Sound (DTS)
  - 5.1 channels stored on a separate CD
  - Synchronized to the film by time codes
  - Has an analog backup
  - First used in 1993

Systems of Motion Picture Sound – Current, cont

- Sony Dynamic Digital Sound (SDDS)
  - Eight full channels
  - Optically stored outside the sprocket holes on both sides of the film
    - Both sides serve as a redundancy
  - Analog optical backup
  - The extra channels are a full channel LFE plus left center and right center behind the screen
